Two Way Analysis of Variance

Professor: Hammou El Barmi Columbia University

- If an experiment has a quantitative outcome and two categorical explanatory variables A and B that are defined in such a way that each experimental unit (subject) can be exposed to any combination of one level of one explanatory variable and one level of the other explanatory variable, then the most common analysis method is two-way ANOVA.
- Because there are two different explanatory variables the effects on the outcome
 of a change in one variable may either not depend on the level of the other
 variable (additive model) or it may depend on the level of the other variable
 (interaction model).

- Goal: compare the means of a single variable at different levels of two factors A and B in scientific experiments.
- Suppose factor A has a levels and factor B has b levels
- In total we have ab treatments
- We assume that each treatment level, we have n_{ij} experimental units and let Y_{ijk} be the kth observation when A=i and B=j
- We will assume first that $n_{ij} \equiv n$ for all (i,j) (we say that the design is balanced)
- We assume that the Y_{ijk} are independent and that

Let

$$\mu_{i\bullet} = \frac{\displaystyle\sum_{j=1}^b \mu_{ij}}{b}, \quad \mu_{\bullet j} = \frac{\displaystyle\sum_{i=1}^a \mu_{ij}}{a}, \quad \mu_{\bullet \bullet} = \frac{\displaystyle\sum_{i=1}^a \displaystyle\sum_{j=1}^b \mu_{ij}}{ab}$$

we can represent the means as follows

		В					
		B_1	B_2		B_b		
	A_1	μ_{11}	μ_{12}		μ_{1b}	μ_{1ullet}	
	A_2	μ_{21}	μ_{22}		μ_{2b}	$\mu_{2\bullet}$	
Α	:		•	•	•		
				•	•		
	:	:		:	:	:	
	A_a	μ_{a1}	μ_{a2}		$\mu_{\sf ab}$	$\mu_{2\bullet}$	
		$\mu_{\bullet 1}$	$\mu_{ullet 2}$		$\mu_{ullet b}$	μ_{ullet}	

Let

$$\bar{Y}_{ij\bullet} = \frac{\sum_{k=1}^{n} Y_{ijk}}{n} \quad \bar{Y}_{\bullet j\bullet} = \frac{\sum_{i=1}^{a} \sum_{k=1}^{n} Y_{ijk}}{an}$$

$$\bar{Y}_{i\bullet\bullet} = \frac{\sum_{j=1}^{b} \sum_{k=1}^{n} Y_{ijk}}{kn} \quad \bar{Y}_{\bullet\bullet\bullet} = \frac{\sum_{i=1}^{a} \sum_{j=1}^{b} \sum_{k=1}^{n} Y_{ijk}}{abn}$$

Let also

$$SST = \sum_{i=1}^{a} \sum_{j=1}^{b} \sum_{k=1}^{n} (Y_{ijk} - \bar{Y}_{\bullet \bullet \bullet})^{2} \quad SSA = nb \sum_{i=1}^{k} (\bar{Y}_{i \bullet \bullet} - \bar{Y}_{\bullet \bullet \bullet})^{2}$$

B维度上的组间距离

$$SSB = na \sum_{i=1}^{k} (\bar{Y}_{i \bullet \bullet} - \bar{Y}_{\bullet \bullet \bullet})^2$$
 $SSAB = n \sum_{i=1}^{k} (\bar{Y}_{ij \bullet} - \bar{Y}_{i \bullet \bullet} - \bar{Y}_{\bullet j \bullet} + \bar{Y}_{\bullet \bullet \bullet})^2$ $SSE = \sum_{i=1}^{a} \sum_{j=1}^{b} \sum_{i=1}^{n} (Y_{ijk} - \bar{Y}_{ij \bullet})^2$

Then

SST = SSA + SSB + SSAB + SSE

ANOVA table

Notice that

$$\frac{E(MSA)}{E(MSE)} = 1 \quad \Leftrightarrow \quad \sum_{i=1}^{3} (\mu_{i\bullet} - \mu_{\bullet\bullet})^{2} = 0$$

$$\Leftrightarrow \quad \mu_{1\bullet} = \mu_{2\bullet} = \dots = \mu_{3\bullet}$$

- We should always start with testing the interaction. If interaction is present, then we ignore main effects look at it as one factor with ab levels
- if no interaction, compare levels of A ignoring B and compare levels of B ignoring A

Test for interaction

 H_0 : No interation and H_a : Yes interaction

• The test statistic is

$$F = \frac{MSAB}{MSE}$$

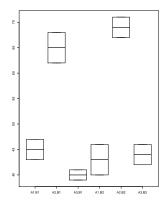

• Reject H₀ if

$$F > F(1-\alpha, (a-1)(b-1), ab(n-1))$$

or if p-value less than $\boldsymbol{\alpha}$

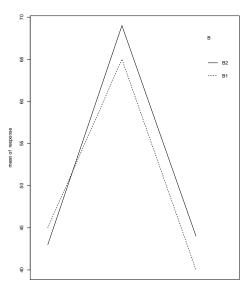

```
> response<-c(47,43, 62,68, 41,39, 46,40,67,71,42,46)

                       10.3
```

```
A ***
B
A:B
```

We have SSA=, 1544SSB=12, SSAB=24, SSE=62. their degrees of freedom are, 2, 1, 2 and 6, respectively

The p-value of the test for interaction is 0.375. We reject H_0 and conclude that there is no interaction.

```
Model without interaction:
```

```
> summary(aov(response~A+B))

Df Sum Sq Mean Sq F value Pr(>F)

A 2 1544 772.0 71.814 7.75e-06

B 1 12 12.0 1.116 0.322

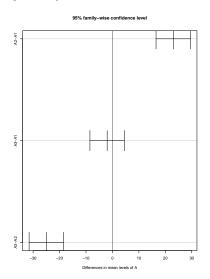

Residuals 8 86 10.8
```

From this output we can conclude that A level means (p-value $|0.05\rangle$) are different but B level means (p-value=0.322) are not (There an A effect but no B effect) We drop B and refit the model

Factor A is significant at $\alpha = 0.01$

We have

$$Y_{ijk} = \mu_{ij} + \epsilon_{ijk}$$

$$= \mu_{\bullet \bullet} + \mu_{i \bullet} - \mu_{\bullet \bullet} + \mu_{\bullet j} - \mu_{\bullet \bullet} + \mu_{ij} - \mu_{i \bullet} - \mu_{\bullet j} + \mu_{\bullet \bullet} + \epsilon_{ijk}$$

$$= \mu_{\bullet \bullet} + \alpha_i + \beta_j + (\alpha \beta)_{ij} + \epsilon_{ijk}$$

where

$$\alpha_i = \mu_{i \bullet} - \mu_{\bullet \bullet}, \quad \beta_j = \mu_{\bullet j} - \mu_{\bullet \bullet} \quad \text{and} \quad (\alpha \beta)_{ij} = \mu_{ij} - \mu_{i \bullet} - \mu_{\bullet j} + \mu_{\bullet \bullet}$$

and

$$\sum_{i=1}^{a} \alpha_{i} = 0, \quad \sum_{j=1}^{b} \beta_{j} = 0, \quad \text{and} \sum_{i=1}^{a} (\alpha \beta)_{ij} = \sum_{j=1}^{b} (\alpha \beta)_{ij} = 0$$

• The α s measure the effect of factor A, the β s measure the effect of factor B and the $(\alpha\beta)_{ii}$ s are the interaction terms

Suppose
$$a = b = 2$$
.

$$\mu_{11} = \mu_{\bullet \bullet} + \alpha_1 + \beta_1 + (\alpha \beta)_{11}$$
 $\mu_{12} = \mu_{\bullet \bullet} + \alpha_1 + \beta_2 + (\alpha \beta)_{12}$
 $\mu_{21} = \mu_{\bullet \bullet} + \alpha_2 + \beta_1 + (\alpha \beta)_{21}$
 $\mu_{22} = \mu_{\bullet \bullet} + \alpha_2 + \beta_2 + (\alpha \beta)_{22}$

Note that since

$$\alpha_1 + \alpha_2 = 0, \beta_1 + \beta_2 = 0, (\alpha \beta)_{11} + (\alpha \beta)_{12} = 0, (\alpha \beta)_{21} + (\alpha \beta)_{22} = 0, (\alpha \beta)_{11} + (\alpha \beta)_{21} = 0$$
 and $(\alpha \beta)_{12} + (\alpha \beta)_{22} = 0$ we have

$$\mu_{11} = \mu_{\bullet \bullet} + \alpha_1 + \beta_1 + (\alpha \beta)_{11} \qquad \mu_{12} = \mu_{\bullet \bullet} + \alpha_1 - \beta_1 - (\alpha \beta)_{11}$$

$$\mu_{21} = \mu_{\bullet \bullet} - \alpha_1 + \beta_1 - (\alpha \beta)_{11} \qquad \mu_{22} = \mu_{\bullet \bullet} - \alpha_1 - \beta_1 + (\alpha \beta)_{11}$$

from the model we have

$$\mu_{11} - \mu_{21} = (\mu_{\bullet \bullet} + \alpha_1 + \beta_1 + (\alpha \beta)_{11}) - (\mu_{\bullet \bullet} - \alpha_1 + \beta_1 - (\alpha \beta)_{11})$$

= $2\alpha_1 + 2(\alpha \beta)_{11}$

and

$$\mu_{12} - \mu_{22} = (\mu_{\bullet \bullet} + \alpha_1 - \beta_1 - (\alpha \beta)_{11}) - (\mu_{\bullet \bullet} - \alpha_1 - \beta_1 + (\alpha \beta)_{11})$$
$$= 2\alpha_1 - 2(\alpha \beta)_{11}$$

So when

$$2\alpha_1 + 2(\alpha\beta)_{11} = 2\alpha_1 - 2(\alpha\beta)_{11}$$

we have

$$\mu_{11} - \mu_{21} = \mu_{12} - \mu_{22} \Leftrightarrow 2\alpha_1 + 2(\alpha\beta)_{11} = 2\alpha_1 - 2(\alpha\beta)_{11}$$

 $\Leftrightarrow (\alpha\beta)_{11} = 0$

If you fix the level of one factor and look at the means, difference does not depend on that level if there is no inteaction

In general

$$\mu_{ij} - \mu_{i'j} = \mu_{ii'} - \mu_{i'j'}$$
 for all $i, i', j, j' \Leftrightarrow (\alpha \beta)_{ij} = 0$ for all (i, j)
